

Looking for Resonances under the LHC Lamppost

K.C. Kong
University of Kansas

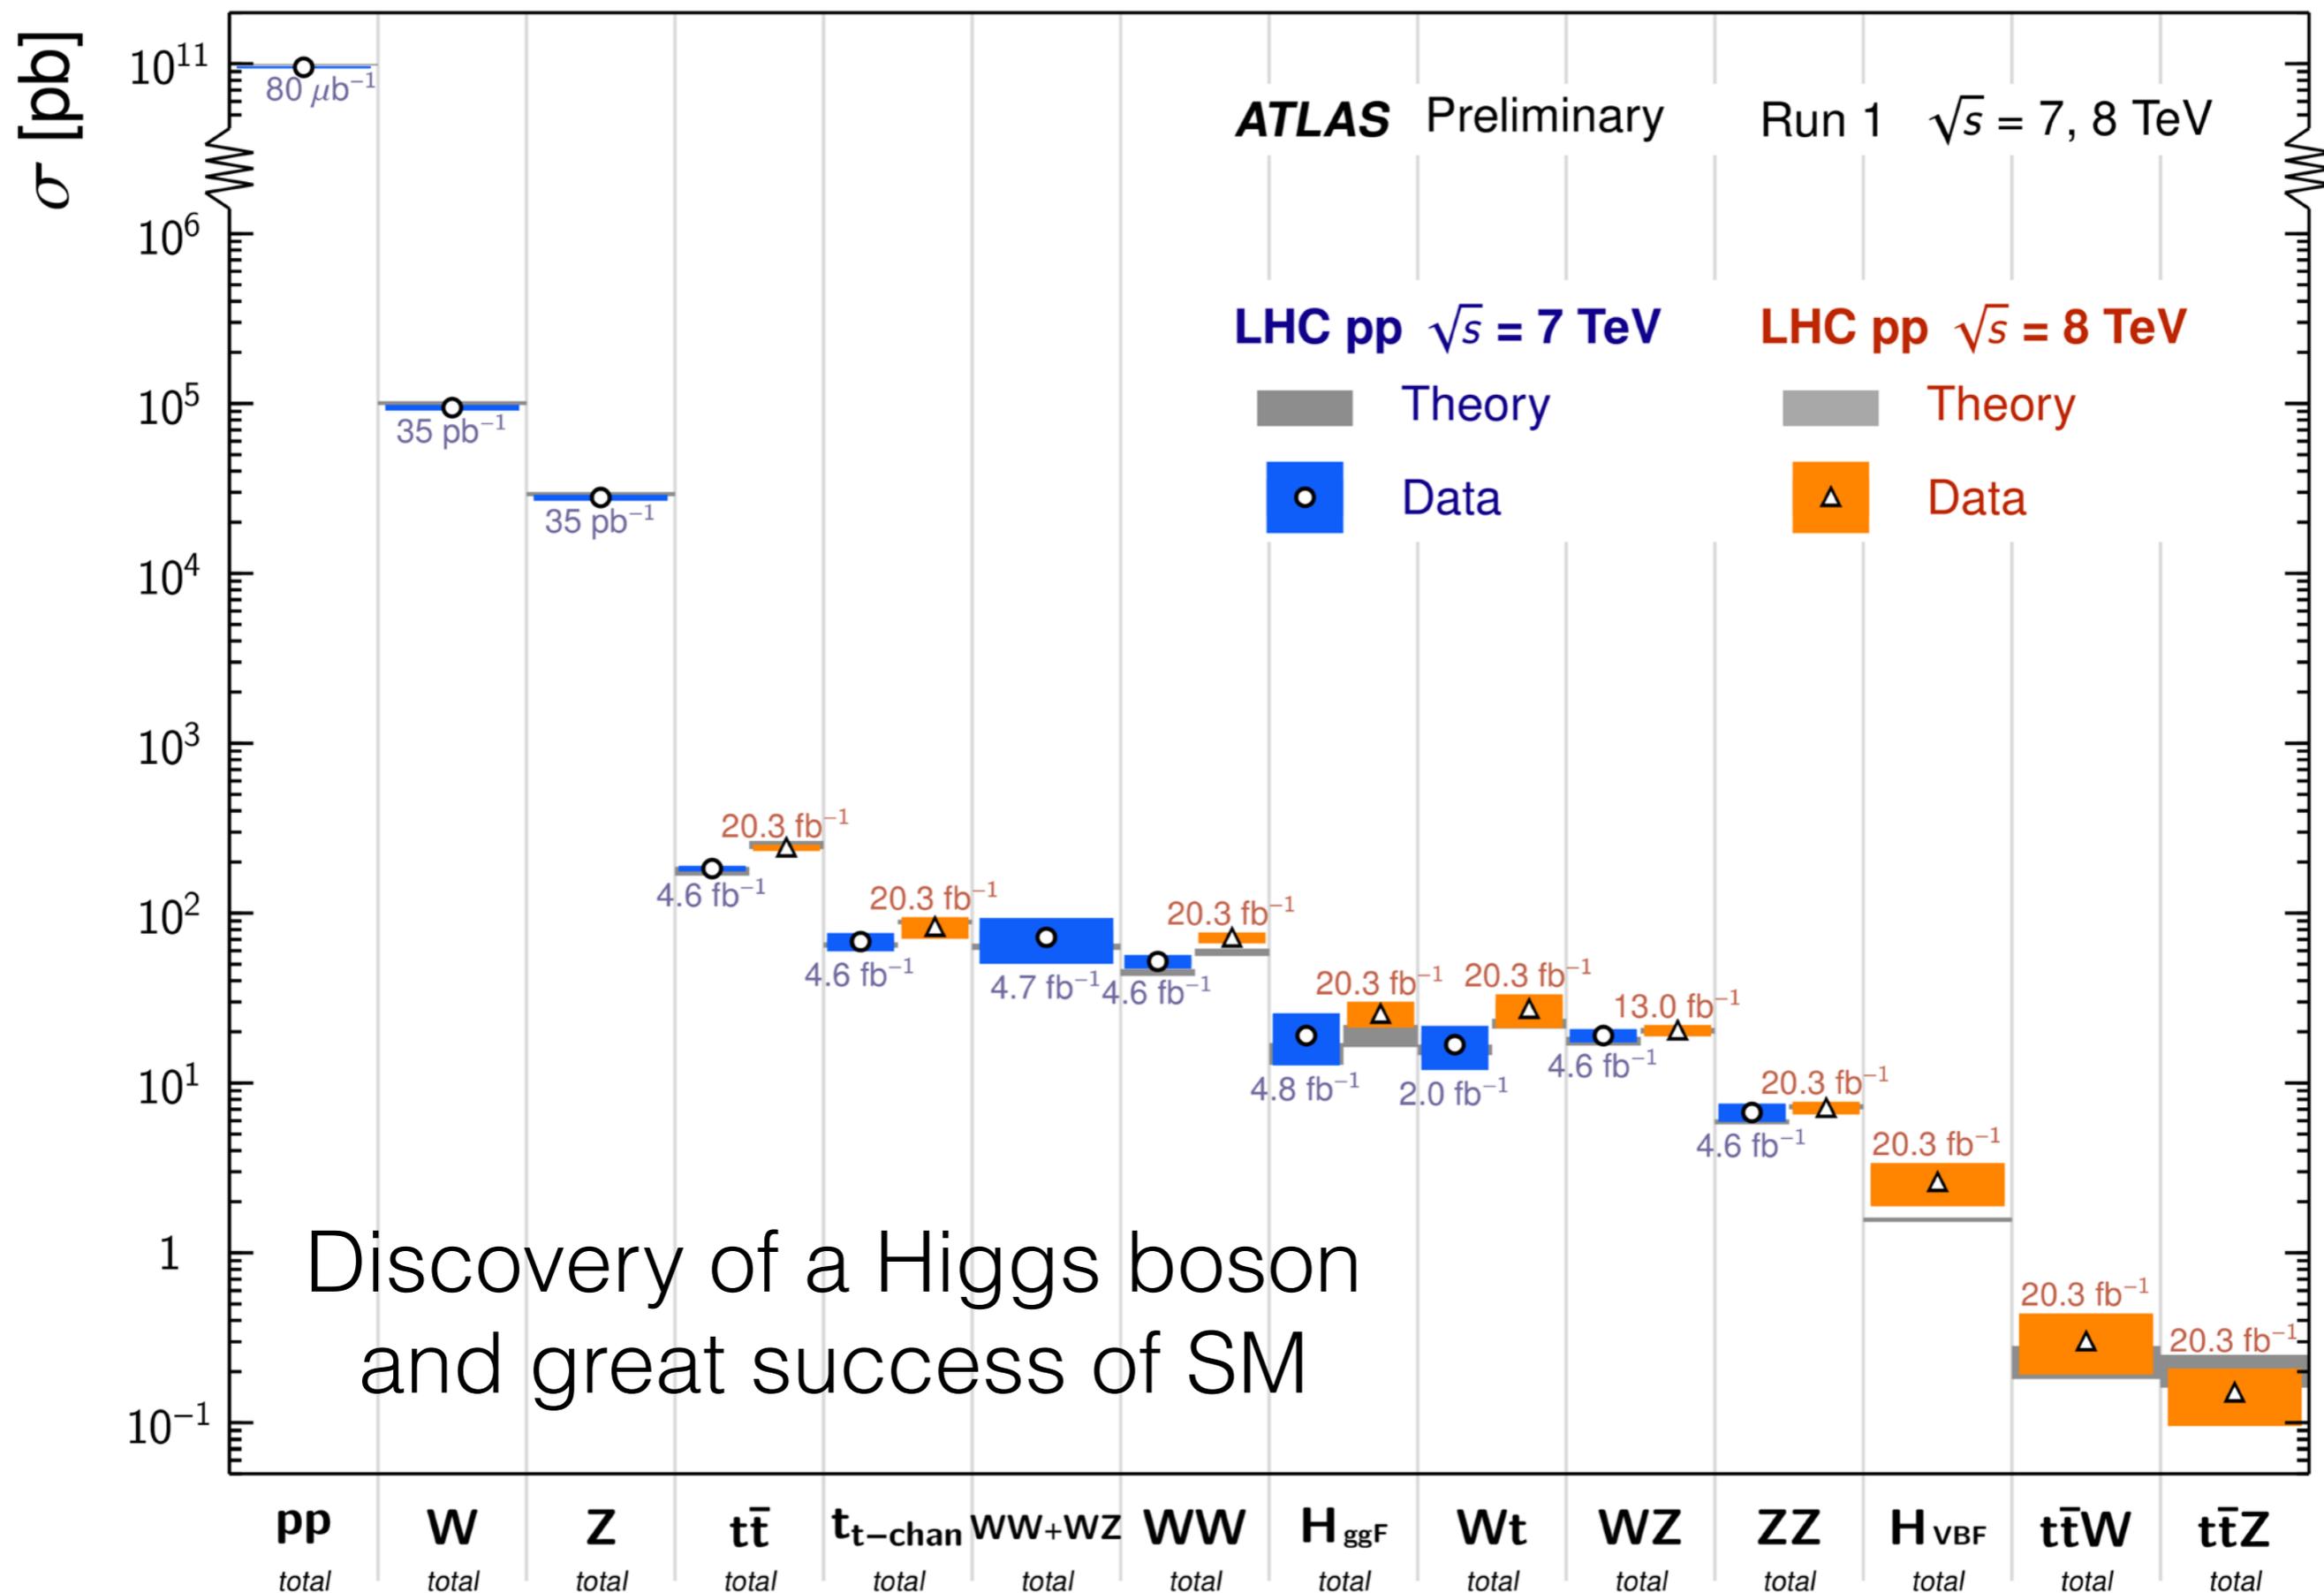

TRIUMF Theory Workshop on
**Searches for New Phenomena
at the Upgraded LHC**

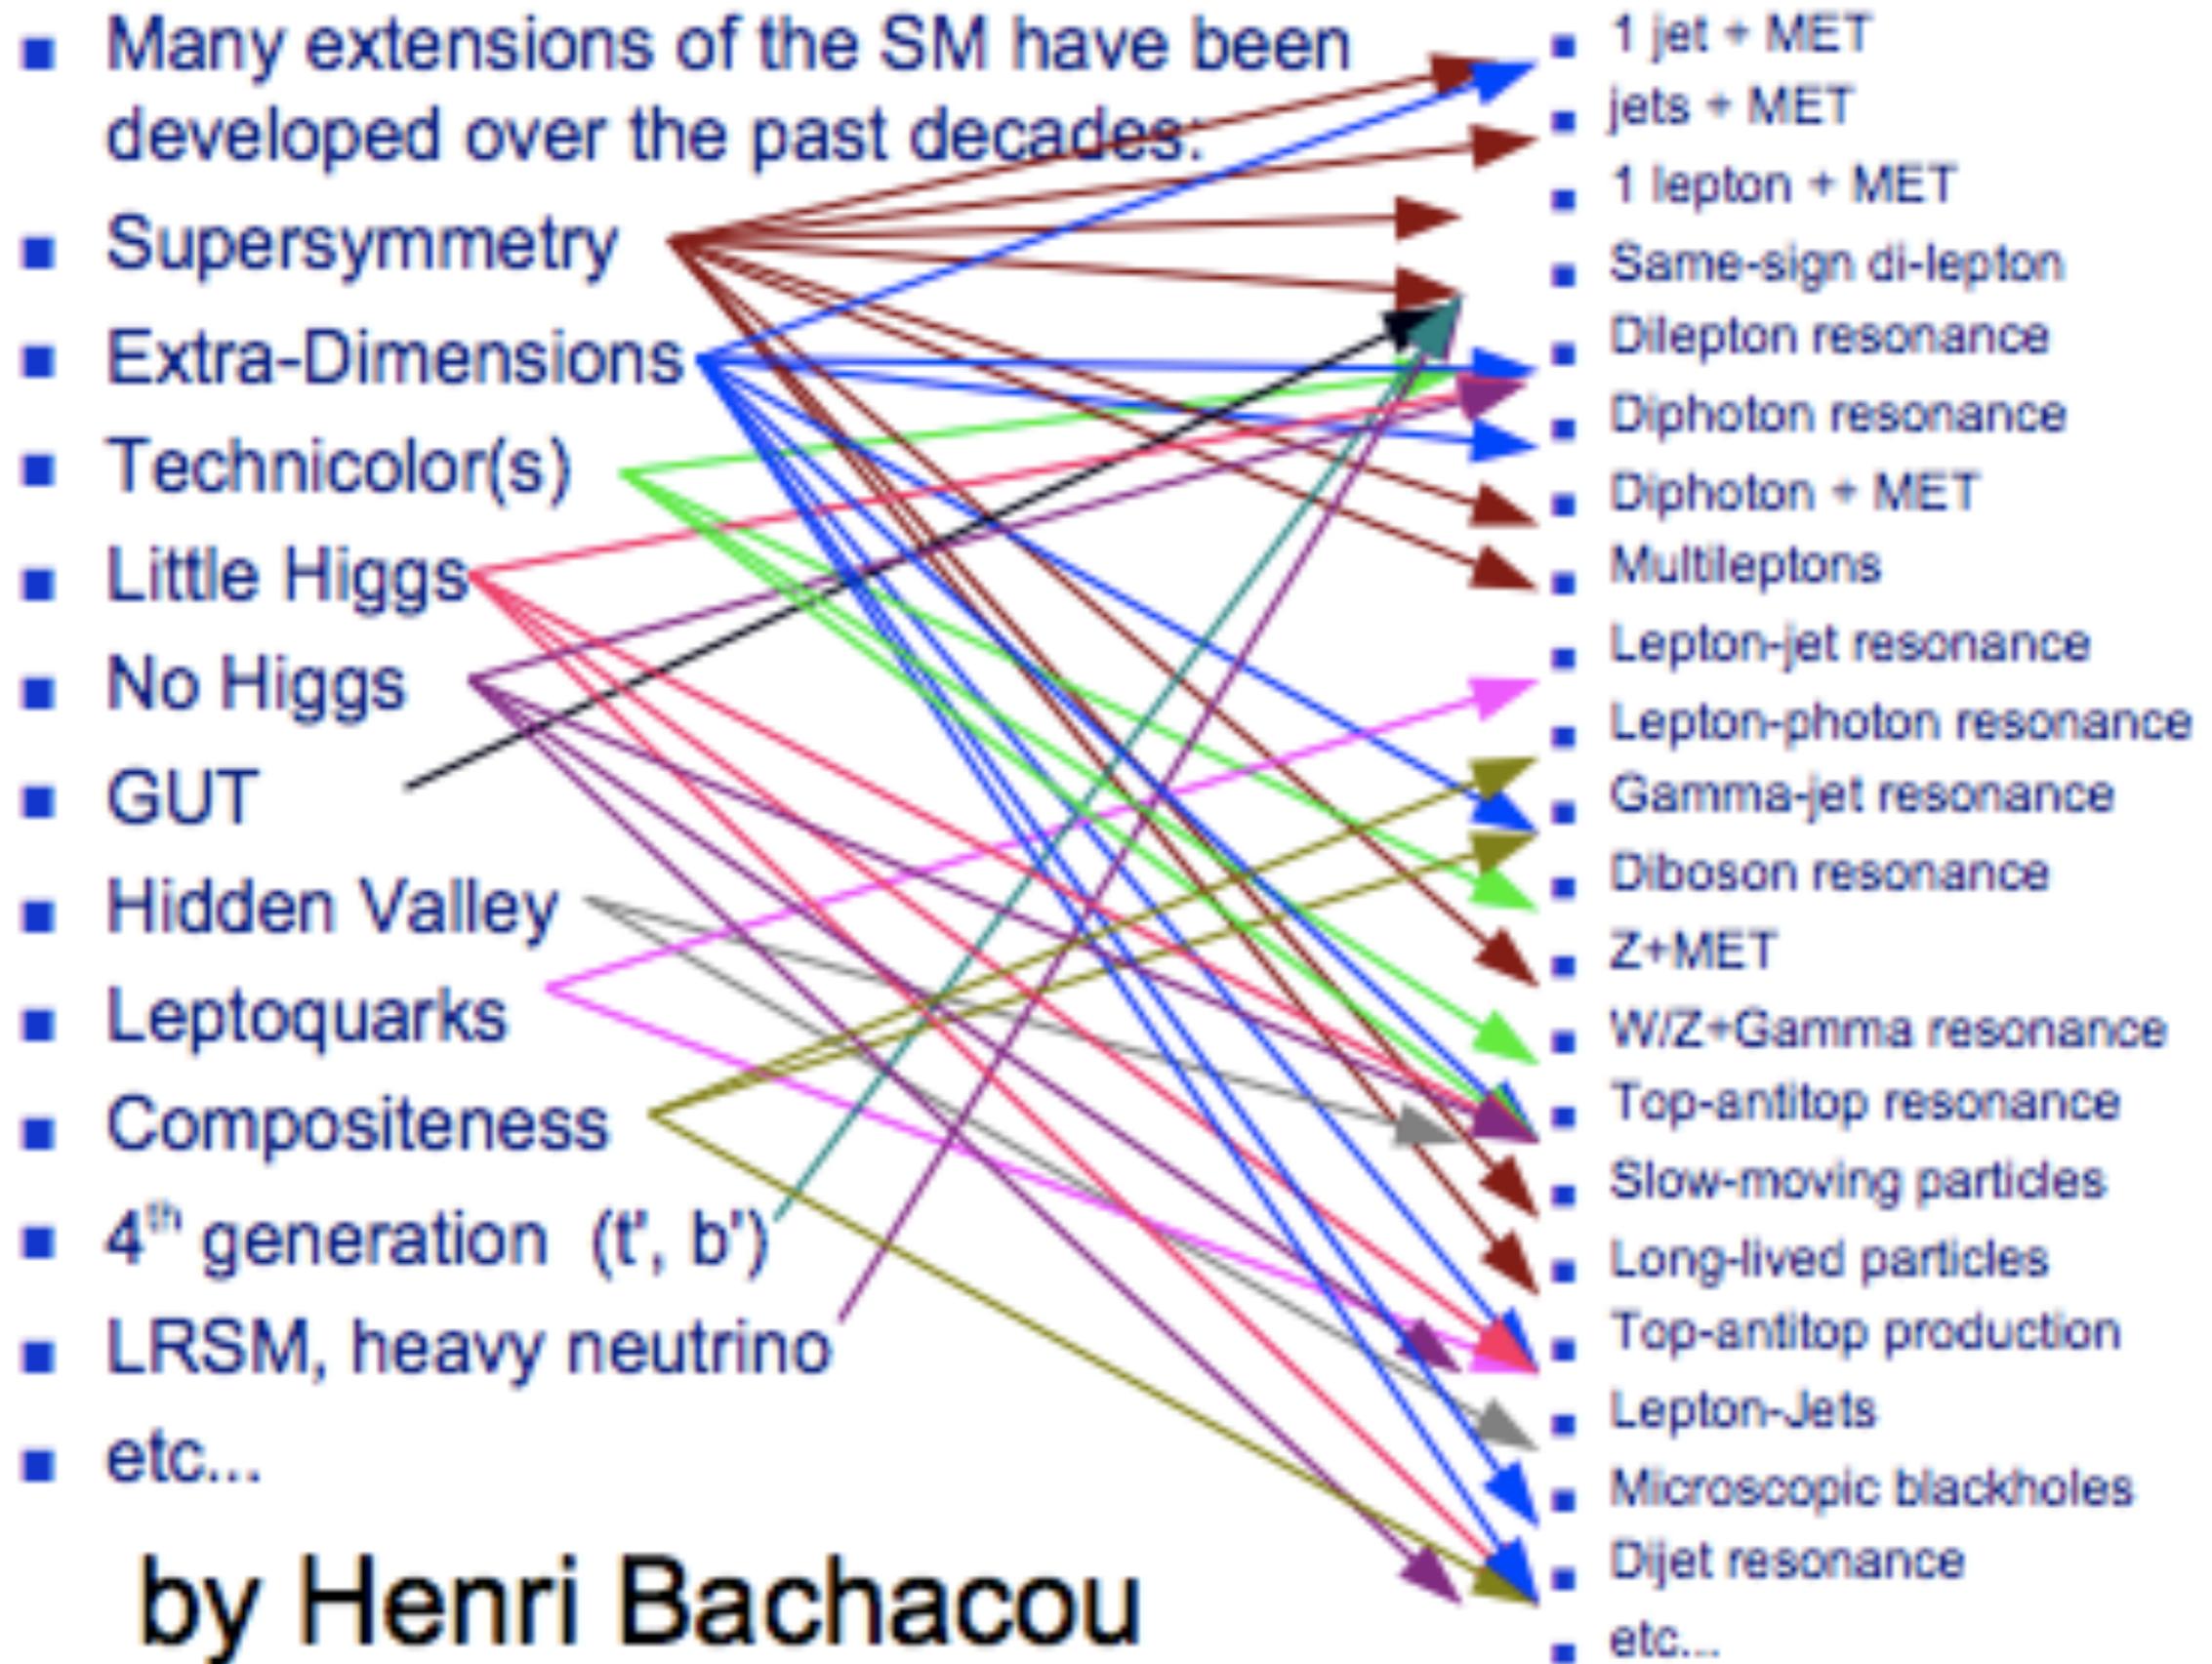

September 8-10, 2014, Vancouver, BC

Standard Model Total Production Cross Section Measurements

Status: July 2014

And yes, we are searching for a new phenomena...

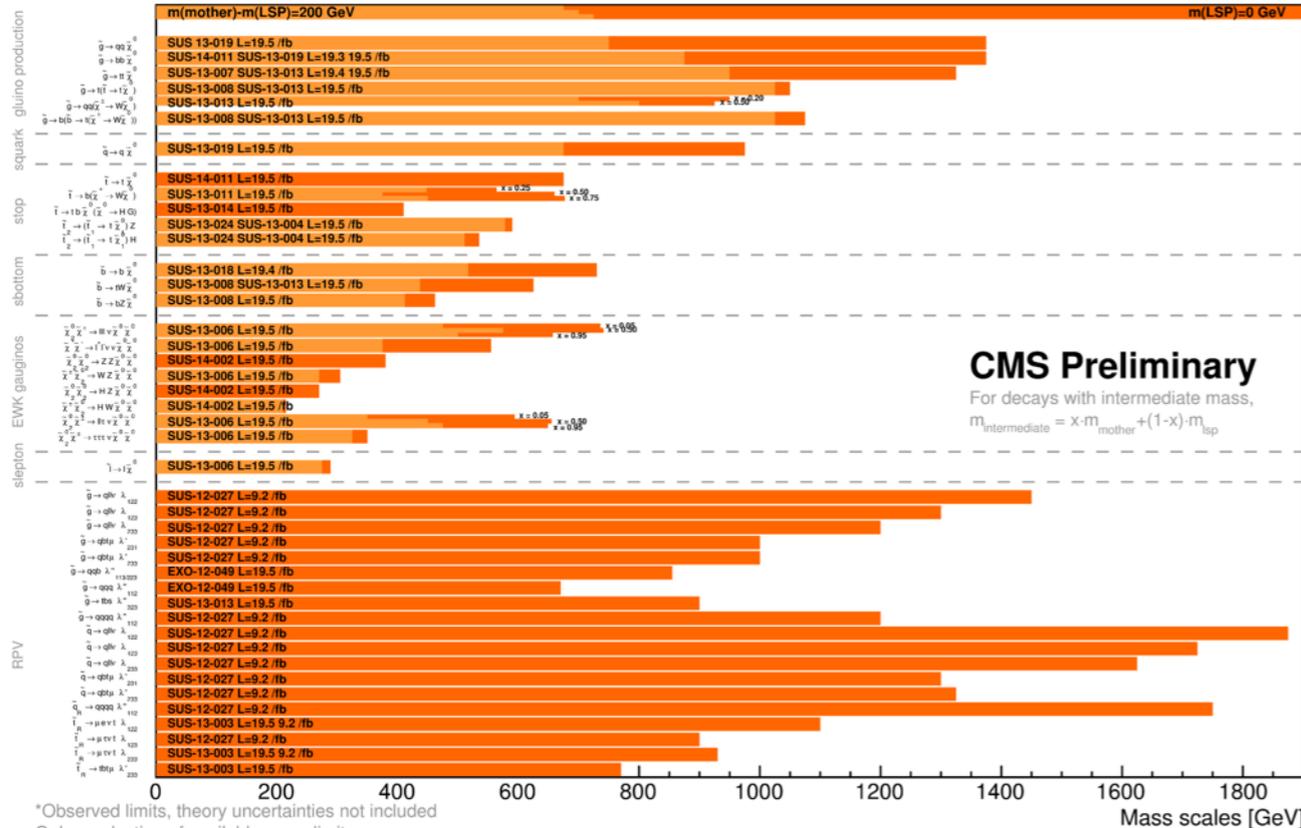

Which BSM model is 'right'?

- There is no right / wrong as far as hypothetical models are concerned (my subjective opinion).
 - Go to a major conference next year to hear the exact opposite for each model.
- Hopefully the LHC will point us to the right direction.
- Until then, better to keep all options open.
- And that is exactly what experimental collaborations are doing.

Summary of CMS SUSY Results* in SMS framework

ICHEP 2014

*Observed limits, theory uncertainties not included
Only a selection of available mass limits
Probe *up to* the quoted mass limit

ATLAS SUSY Searches* - 95% CL Lower Limits

Status: ICHEP 2014

ATLAS Preliminary

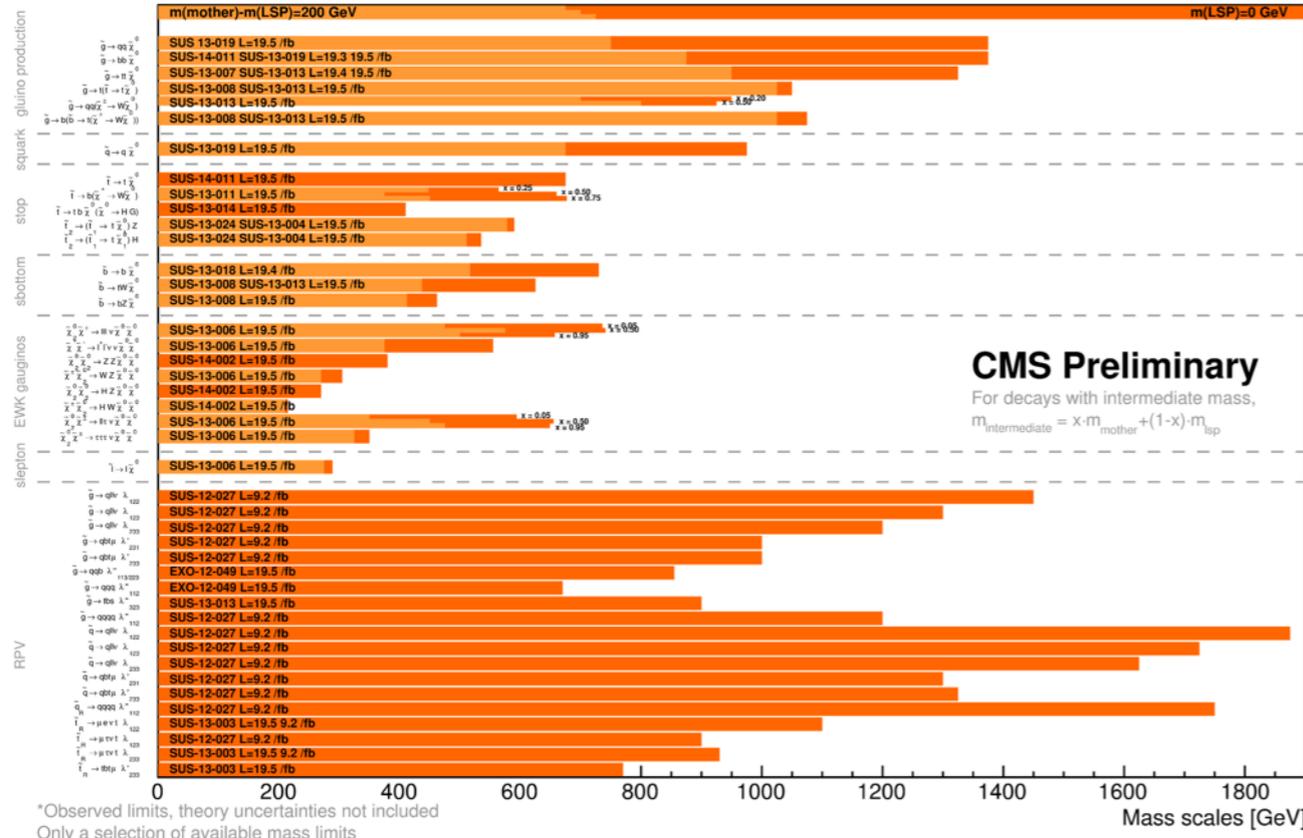

$\sqrt{s} = 7, 8 \text{ TeV}$

Table 1: Examples of di-object. F' = ‘excited fermion’, \cancel{R} = ‘R-parity violation’, LQ = ‘Lepto-Quark’. Numbers in subscript indicate that particles have extra dimensional origin. Supersymmetric particles have \sim as usual.

This is NOT a complete list at all!

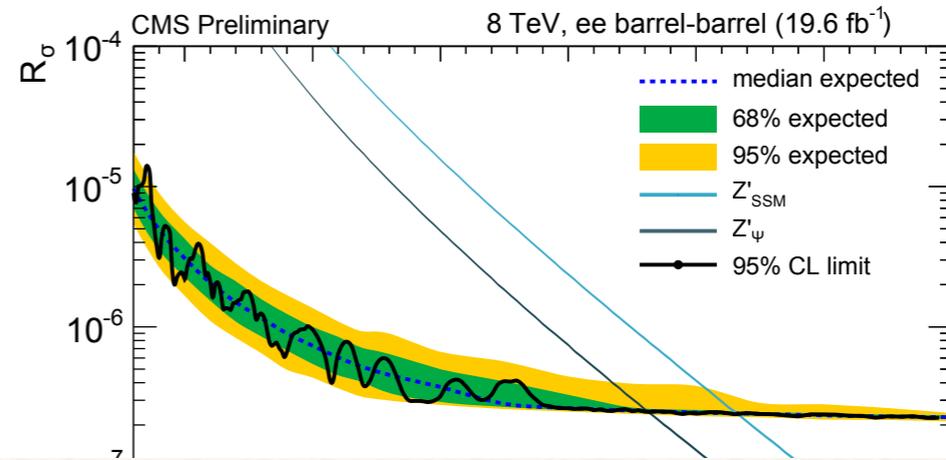

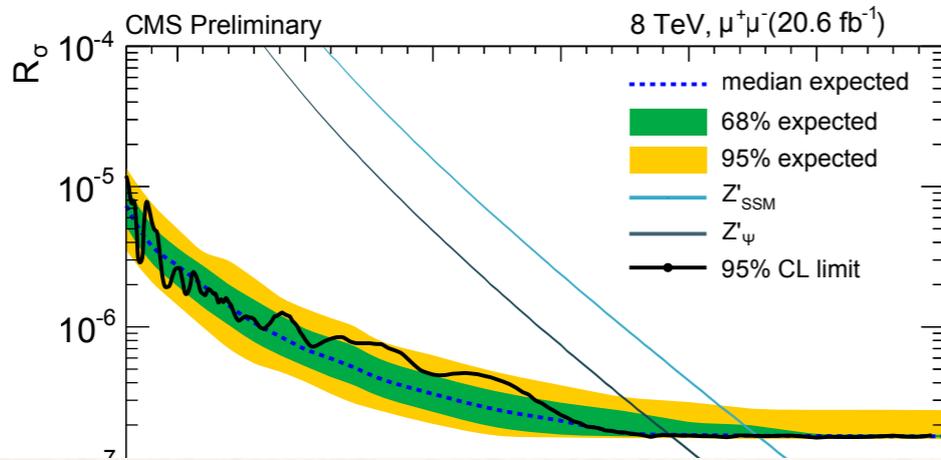

A few comments

- Table tells us how a di-object decays. No information on its production.
- Search strategy can be different depending on the mass scale and details of each model.
- One can further classify
 - in terms of electric charge (SS/DS), color charge (single, triplet, octet, sextet etc), Lorentz symmetry (scalar/fermion/vector)
 - e and mu are different. tau is special. Gluon and quarks are different.
- Table can be extended with THREE reconstructed objects.
- Reconstruction of a resonance in MET channel is challenging.
 - Various ideas exist: MT2, M2 etc. (See Doojin's talk)

- Certainly the table is not complete and can be improved. Nevertheless we are covering these boxes pretty well.
- In fact, almost all spots are considered at least in theory.
- Some channels are looked at experimentally and some are not.
- However, we always have to remember what assumptions are made behind each analysis.
- We cover final states reasonably but we make strong assumptions on their production.
- We will take a look at three examples of resonances with non-standard production mechanism that might escape current analysis.
 - dilepton, dijet and $t\bar{t}$ resonances.

dilepton resonance

Fermion Pairs

Final states with bosons

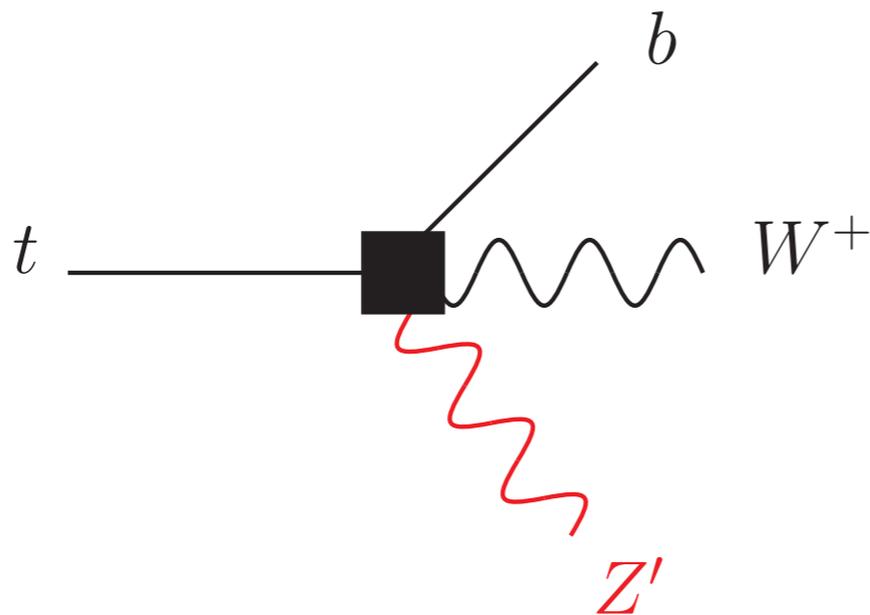

Is a very light dilepton resonance searched for?

Perhaps dilepton resonance exists in the low mass region
(not in the high mass side).

Perhaps we were going in the wrong direction.

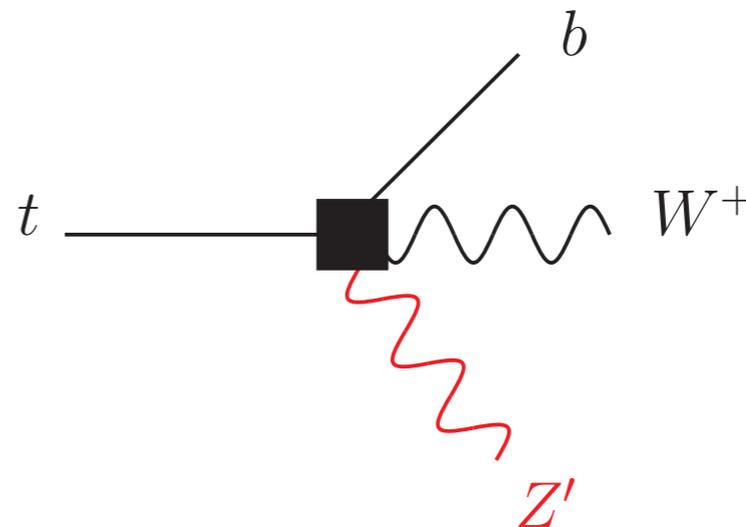

Maybe dilepton resonance is produced via top quark,
not from qqbar annihilation.

- $M_{Z'}$ prime $\sim O(1-10)$ GeV

Charged Higgs + Z'

- Dark Z + 2HDM (type I)
- Charged Higgs: H^+/H^- ($m_W < m_{H^+} < m_{\text{top}}$)
- Neutral Higgses: h , H and A
- Dark Z: Z_d of mass $O(1-10)$ GeV (1, 2 and 5 GeV)

Dark Zprime (Zd)

- A gauge boson of a new dark U(1).
- Light Zd with weak couplings to SM may address various anomalies such as positron data, muon g-2 etc.
- Zd has no direct couplings to SM. It couples to SM via kinetic mixing + extra mass mixing.
- Exact couplings depend on details of model, especially on higgs sector.
- It opens up exotic Higgs decays and provides interesting collider signatures!

$$\begin{aligned}\mathcal{L}_{\text{dark } Z} &= -(\varepsilon e J_{em}^\mu + \varepsilon_Z g_Z J_{\text{NC}}^\mu) Z'_\mu \\ &= \bar{f} (g_V \gamma^\mu - g_A \gamma^\mu \gamma^5) f Z'_\mu\end{aligned}$$

$$\begin{aligned}g_V &= -\varepsilon e Q_f - \varepsilon_Z g_Z \left(\frac{1}{2} T_{3f} - Q_f \sin^2 \theta_W \right) \\ g_A &= -\varepsilon_Z g_Z \left(\frac{1}{2} T_{3f} \right),\end{aligned}$$

$$|\varepsilon| \lesssim 10^{-2} \quad \varepsilon_Z \equiv \delta \frac{m_{Z'}}{m_Z}$$

$$|\delta| \lesssim 10^{-2}$$

Charged Higgs + Z_d

- In 2HDM, FCNC constraints can be addressed by a new $U(1)$, under which Higgs doublets carry different charges.
- Such a scenario may introduce tree-level HWZ_{prime} coupling.
- For a light “dark” Z model (with mass < 10 GeV), charged Higgs may decay dominantly into $W + Z_d$ (for mass $< m_{\text{top}}$)
- For a Z_d with $O(1)$ GeV mass, BR into leptons is large.
- At LHC, such a Z_d can be boosted, and two leptons from Z_d decay appear as a Lepton-Jet.

Davoudiasl, Marciano, Ramos, Sher, 2014

Kong, Lee, Park, 2014

Charged Higgs (H^\pm) decay

- For $M_{H^\pm} < m_{\text{top}}$, dominant decays are into cs and tau-neutrino in usual 2HDM.

$$\Gamma(H^\pm \rightarrow \nu\tau^\pm) \simeq \frac{m_{H^\pm}}{8\pi v^2} \frac{m_\tau^2}{\tan^2 \beta}$$

- For (i), the lighter Higgs boson is SM-like. $H^\pm W^\mp Z^0$ coupling is small but $H^\pm \text{ Br to } WZ^0$ can be large.

$$\Gamma(H^\pm \rightarrow WZ') \simeq \frac{m_{H^\pm}^3}{16\pi v^2} (\sin \beta \cos \beta_d)^2 \left(1 - \frac{m_W^2}{m_{H^\pm}^2}\right)^3$$

- For (ii), the charged Higgs can decay to the lighter Higgs. In the decoupling limit ($\alpha = \pi/2$ or $-\pi/2$), the heavier Higgs is SM-like.

$$\Gamma(H^\pm \rightarrow Wh) \simeq \frac{\sin^2 \beta}{16\pi v^2} \frac{1}{m_{H^\pm}^3} \lambda^{3/2}(m_{H^\pm}^2, m_W^2, m_h^2)$$

- $\text{Br}(h \rightarrow Z^0 Z^0) \sim 1$, since h does not couple to SM fermions. (Type I)

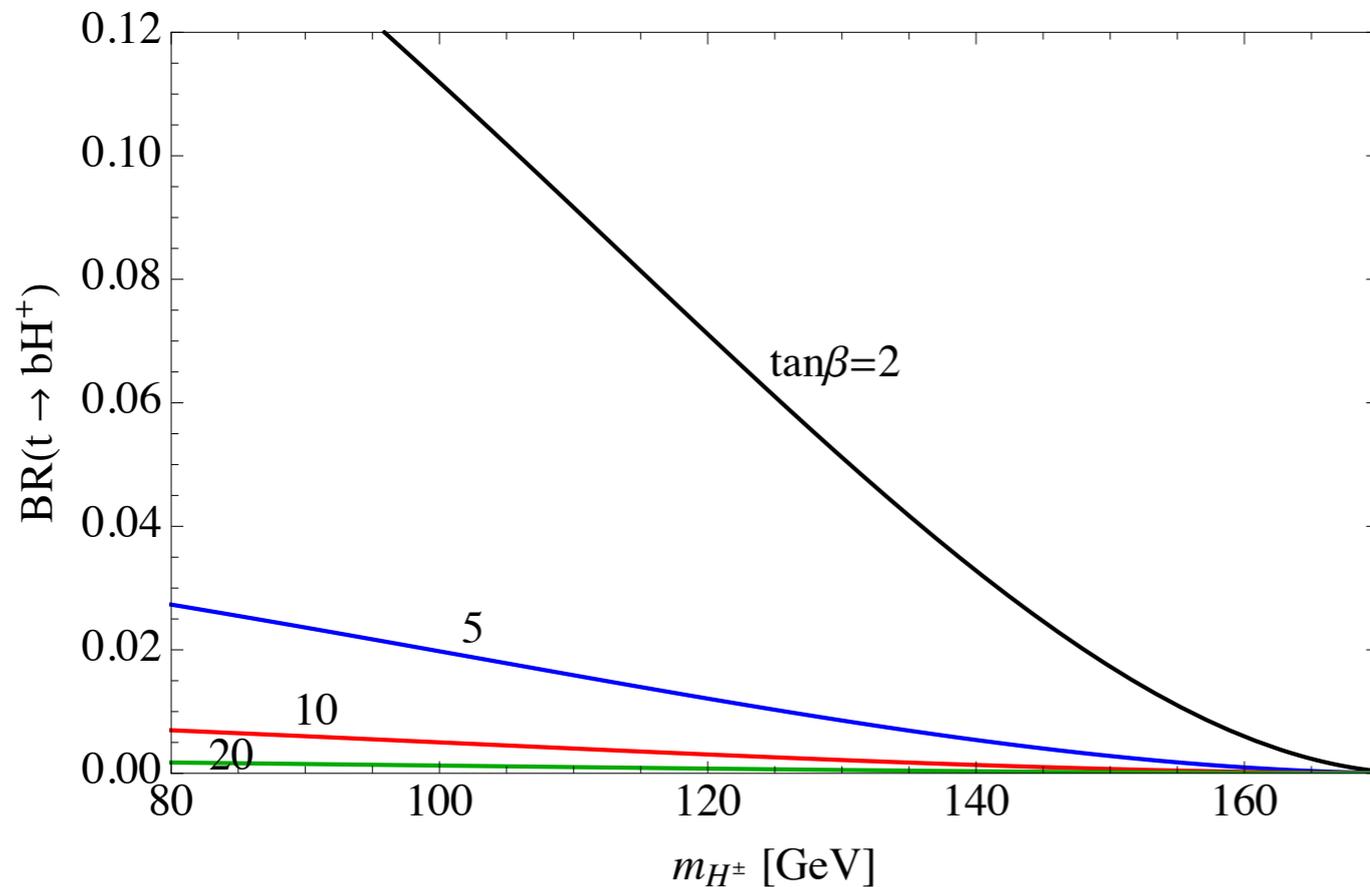

$$Y \equiv \text{BR}(H^\pm \rightarrow W + Z' \text{'s}),$$

- In both (i) and (ii), over much of parameter space, $Y \sim 1$. Whether (i) or (ii) dominates depends on the mass of Higgs boson, especially mass of non-SM Higgs.

- (i) $t \rightarrow bH^\pm \rightarrow bW + Z'$
(through $H^\pm W^\mp Z'$ coupling),
- (ii) $t \rightarrow bH^\pm \rightarrow bW + h \rightarrow bW + Z'Z'$
(with a light non-SM Higgs boson h),
- (iii) $t \rightarrow bW^* \rightarrow bW + Z'$
(through $Z'WW$ coupling),
- (iv) $t \rightarrow bW^* \rightarrow bW + h \rightarrow bW + Z'Z'$
(through hWW coupling).

- In principle, $t \rightarrow qZ'$ (with $q = u, c$) is possible.

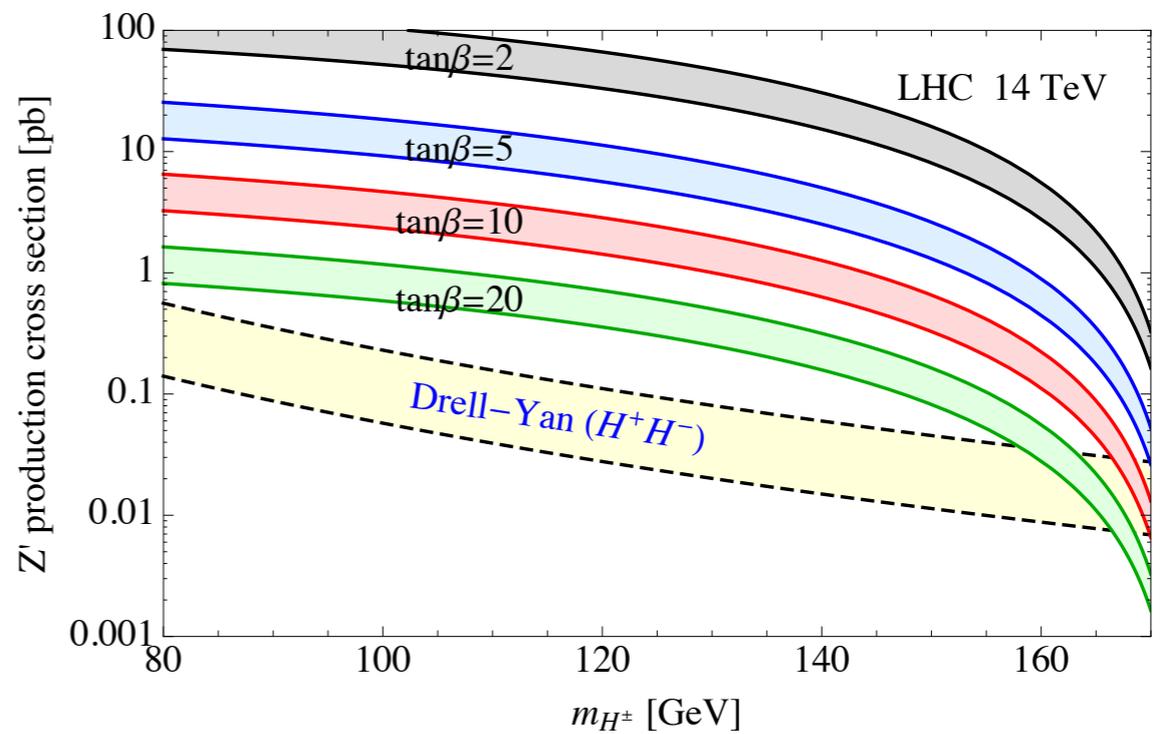

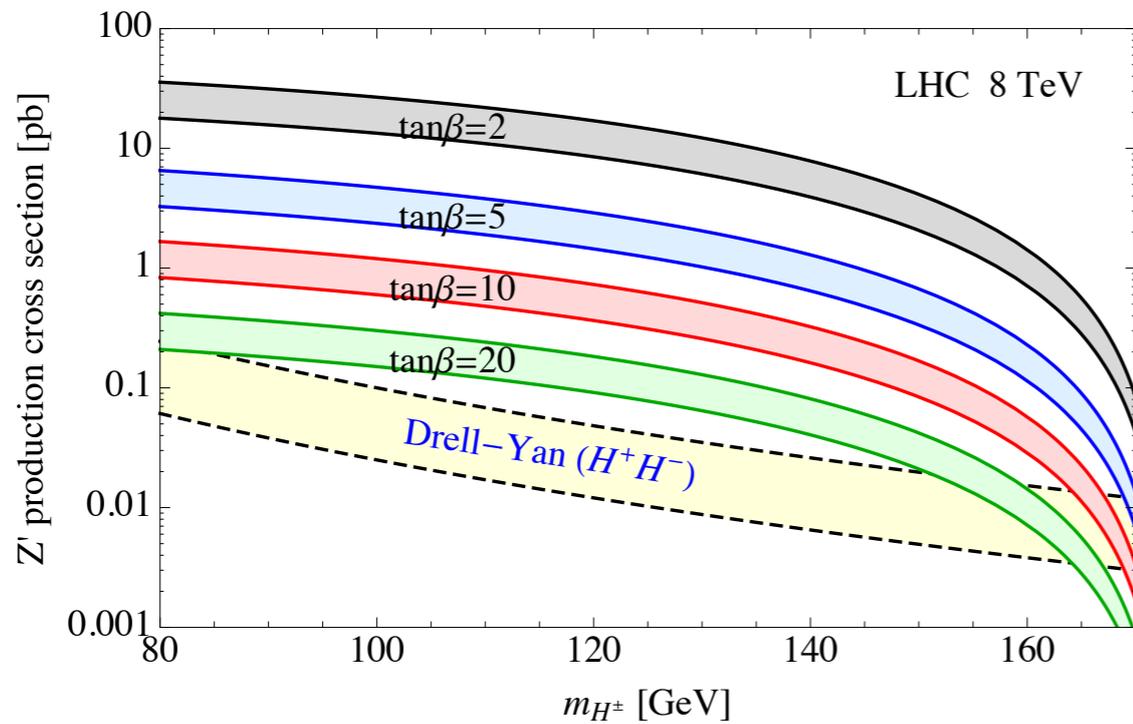

Top decay into Zd via H+

- For numerical analysis, we focus on
 - (i) $t \rightarrow bH^+ \rightarrow bW + Z'$
(through $H^\pm W^\mp Z'$ coupling).
- Higher BR for lower tan(beta).
- Current limit allows O(1)% branching fraction.

$$\begin{aligned}
 \text{BR}(t \rightarrow bH^+) &\simeq \frac{\Gamma_{t \rightarrow bH^+}}{\Gamma_{t \rightarrow bW} + \Gamma_{t \rightarrow bH^+}} \\
 &\simeq \left(\frac{m_t^2 - m_{H^\pm}^2}{m_t^2 - m_W^2} \right)^2 \frac{1/\tan^2 \beta}{1 + 2m_W^2/m_t^2}
 \end{aligned}$$

Production of Zd

- Zd production in DY ($pp \rightarrow H^+H^- \rightarrow WW + Z'Z'$) and top pair production,

$$\sigma(pp \rightarrow bW \bar{b}W + Z's) \simeq \sigma_{t\bar{t}} 2X \quad X = \text{BR}(t \rightarrow bH^+) Y$$

- The band indicates $\text{BR}(H^+ \rightarrow W Z) = 0.5-1$ range. $Y = \text{BR}(H^\pm \rightarrow W Z') = 0.5 - 1$
- Cross section at 14 TeV is about 4 times larger than that at 8 TeV.
- For a low $\tan(\beta)$, top quark production is important.

Lepton Pair from Z_d decay

- Light Z_d cannot be reconstructed with the usual lepton tagging.
- $\Delta R \simeq \Delta\eta$ since $\Delta\phi$ is peaked at 0.

$$\begin{aligned} m_{\ell^+\ell^-}^2 &= 2P_{T_1}P_{T_2}(\cosh\Delta\eta - 1) \\ &\simeq 2P_{T_1}P_{T_2}(\cosh\Delta R - 1) \end{aligned}$$

- For a moderate lepton tagging efficiency, most analysis require

$$P_{T(e)}^{\min} = 10 \text{ GeV}, \quad P_{T(\mu)}^{\min} = 5 \text{ GeV}.$$

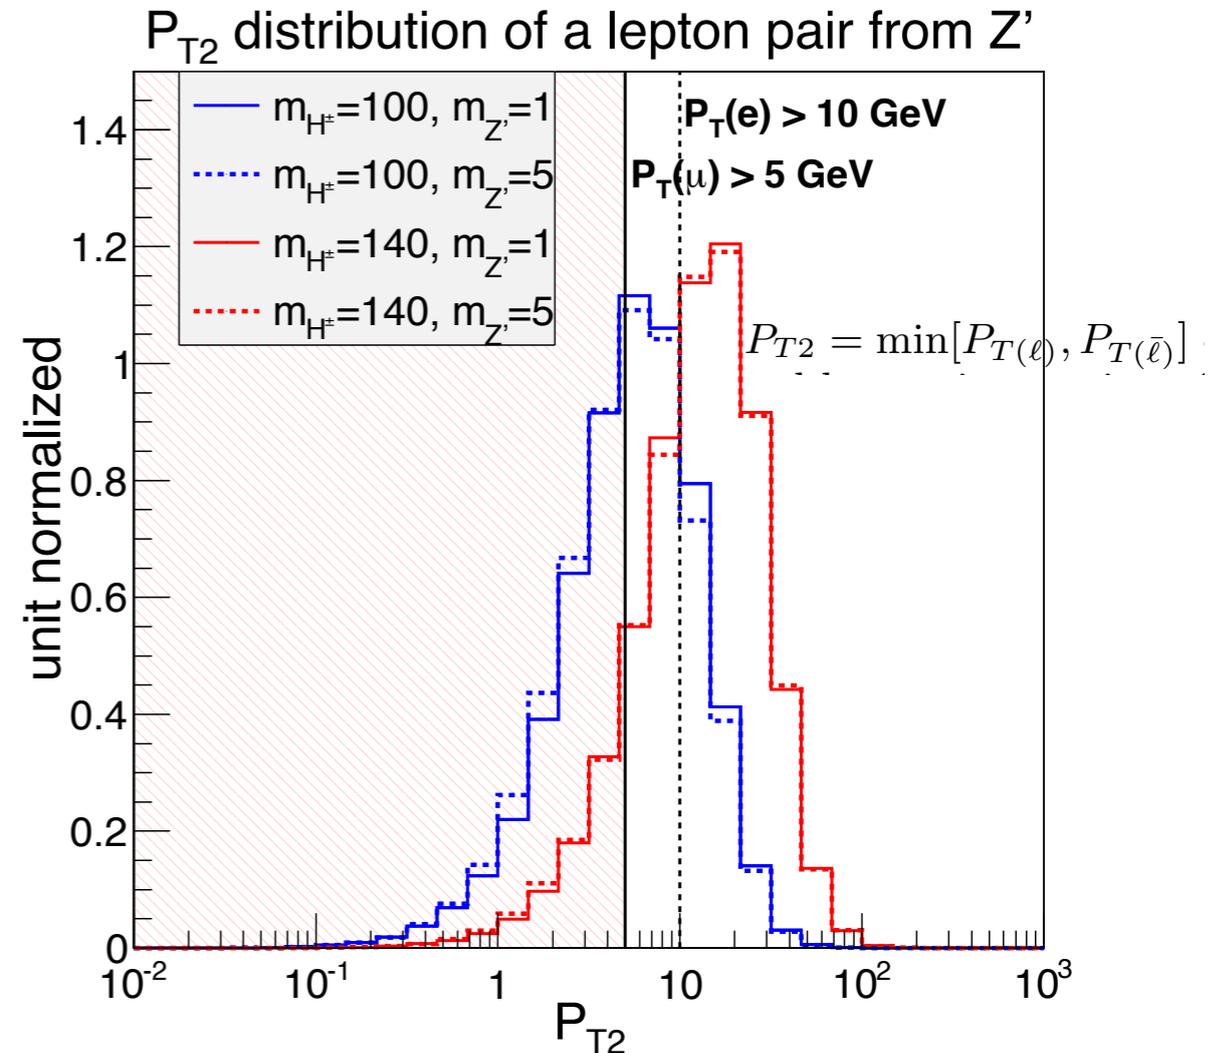

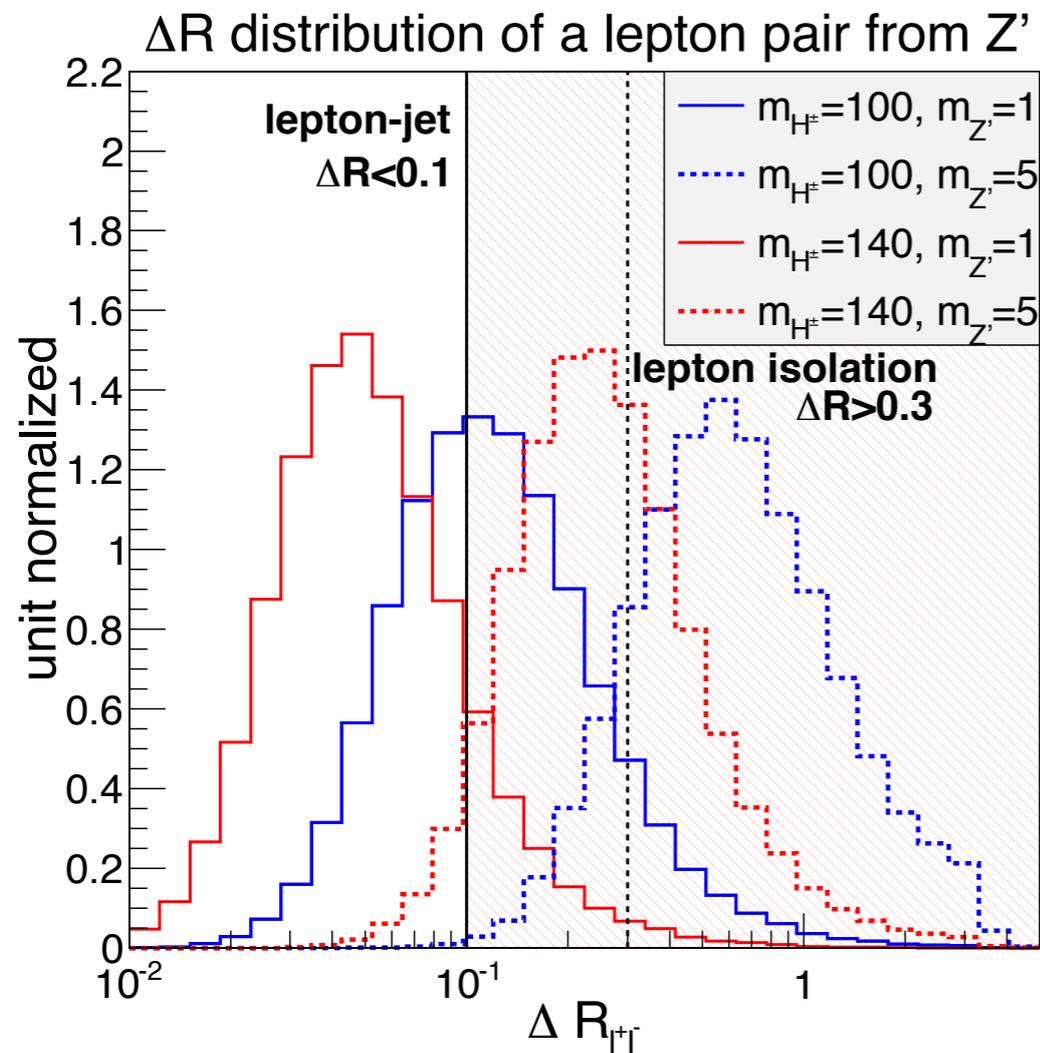

- With an isolation requirement of $\Delta R > 0.3$,

$$\begin{aligned} m_{ee} &> \sqrt{2P_{T(e)}^{\min}P_{T(e)}^{\min}(\cosh(0.3) - 1)} \simeq 3 \text{ GeV}, \\ m_{\mu\mu} &> \sqrt{2P_{T(\mu)}^{\min}P_{T(\mu)}^{\min}(\cosh(0.3) - 1)} \simeq 1.5 \text{ GeV}. \end{aligned}$$

- Conventional analysis would miss Z_d lighter than 3 (1.5) GeV in the dielectron (dimuon) channel.

Lepton Pair from Z_d decay

- Light Z_d cannot be reconstructed with the usual lepton tagging.

$$\Delta R^{(\text{peak})} \sim \cosh^{-1} \left(\frac{2m_{Z'}^2}{(E_\ell^{(\text{cusp})})^2} + 1 \right)$$

$$\eta_{H^\pm} = \cosh^{-1} \left(\frac{m_t^2 + m_{H^\pm}^2 - m_b^2}{2m_t m_{H^\pm}} \right),$$

$$\eta_{Z'} = \cosh^{-1} \left(\frac{m_{H^\pm}^2 + m_{Z'}^2 - m_W^2}{2m_{Z'} m_{H^\pm}} \right).$$

$$E_\ell^{(\text{max})} = \frac{m_{Z'}}{2} e^{(\eta_{Z'} + \eta_{H^\pm})}$$

$$E_\ell^{(\text{cusp})} \equiv \frac{m_{Z'}}{2} e^{|\eta_{Z'} - \eta_{H^\pm}|}$$

$$P_T^{\text{peak}} \equiv \frac{1}{2} E_\ell^{(\text{cusp})}$$

Improved Lepton Selection

1. At least two same flavor leptons with $P_T > 10$ GeV (electron), 5 GeV (muon) and in a cone of $\Delta R < 0.1$.
 - For our study, we use FeynRules, MG4, PYTHIA, and Delphes.
2. Isolation: Hadronic and leptonic isolation of $\sum P_T < 3$ GeV in $0.1 < \Delta R < 0.4$.
 - 60%-75% of b-tagging efficiency, depending on PT and ETA, following CMS CSVM tagging.
3. Invariant mass cut on lepton-jet: $|m_{LJ} - m_{Z'}| < 0.2 \times m_{Z'}$.
 - We make minor changes in the Delphes module to include the non-zero muon mass in the original routine.
 - We add the lepton-jet class in the Delphes, following above definitions.
 - Use anti-kt with DeltaR < 0.5. Require at least one b-tagged jet and above LJ conditions.
 - For numerical study, we use $X = 0.001$ and $\text{BR}(Z' \rightarrow \ell^+ \ell^-) = 0.2$

$$\sigma(pp \rightarrow bW \bar{b}W + Z's) \simeq \sigma_{t\bar{t}} 2X \quad X = \text{BR}(t \rightarrow bH^+) Y$$

Signal and Backgrounds

- Dilepton channel
 - $pt < 20$ GeV, $\eta < 2.5$ for electron and $pt > 20$ GeV, $\eta < 2.1$ for muon
 - veto OSSF with $m_{ll} < 20$ GeV and $|M_{Zd} - m_{ll}| < 15$ GeV, $met > 40$ GeV
 - at least two jets with $pt > 30$ GeV, $\eta < 2.5$
- Semileptonic channel
 - $pt > 30$ GeV, $\eta < 2.5$ for electron and $pt > 26$ GeV, $\eta < 2.1$ for muon
 - at least four jets with $pt_1, pt_2 > 45$ GeV, $pt_3, pt_4 > 35$ GeV.
- Hadronic channel
 - at least 6 jets, $pt > 30$ GeV, $\eta < 2.4$.
 - CMS requires $pt_1, pt_2, pt_3, pt_4 > 60$ GeV, $pt_5 > 50$ GeV, $pt_6 > 30$ GeV, and additional constrains for two b-tagged jets and a kinematic for mass reconstruction of tops and W.
- Backgrounds: $t\bar{t} + \text{dilepton}$ with $K_{b\text{kind}}=2$. ($K_{\text{sig}}=1.74$ (1.84) at 8 (14) TeV.)

LJ Tagging Efficiencies

LHC [TeV]	$m_{Z'}$ [GeV]	$\epsilon_{\text{LJ}}(\epsilon_{(\text{LJ}+\text{CMS})})$ [%] for signal			Mass range of $m_{\ell+\ell^-}$ [GeV]	$\sigma_{\text{bkg}}^{\text{LO}}$ [pb]	$\epsilon_{\text{LJ}}(\epsilon_{(\text{LJ}+\text{CMS})})$ [%] for background
		$m_{H^\pm} = 100$ GeV	$m_{H^\pm} = 140$ GeV	$m_{H^\pm} = 160$ GeV			
8	1	16.37 (4.18/2.07)	46.77 (10.96/4.51)	52.04 (9.40/3.04)	0.5 – 1.5	0.617	2.05 (0.61/0.28)
	2	3.07 (0.92/0.43)	31.01 (7.64/3.13)	40.74 (7.57/2.50)	1.0 – 3.0	0.157	0.53 (0.19/0.08)
	5	0.02 (0.00/0.00)	2.24 (0.64/0.26)	5.55 (1.25/0.48)	3.0 – 5.0	0.0175	0.32 (0.10/0.04)
14	1	16.38 (4.28/2.02)	44.28 (10.73/4.37)	50.54 (9.44/3.13)	0.5 – 1.5	2.536	2.18 (0.60/0.30)
	2	3.33 (1.11/0.49)	29.73 (7.52/3.13)	39.31 (7.64/2.51)	1.0 – 3.0	0.640	0.57 (0.23/0.11)
	5	0.03 (0.01/0.00)	2.57 (0.76/0.28)	5.90 (1.40/0.47)	3.0 – 5.0	0.0706	0.34 (0.15/0.08)

TABLE III: Lepton-jet tagging efficiency ϵ_{LJ} (%) in $pp \rightarrow bW\bar{b}W + \ell^+\ell^-$ for signal (for given m_{H^\pm} and $m_{Z'}$) and background (from virtual photon and virtual Z boson) at the 8 and 14 TeV LHC. The numbers in parentheses ($\epsilon_{(\text{LJ}+\text{CMS}[1\text{b}])}/\epsilon_{(\text{LJ}+\text{CMS}[2\text{b}])}$) are the efficiencies when we require additional selection cuts, requiring one b -tagged or two b -tagged jets as described in Appendix A 2. Coupling structure of Z' to the lepton does not give a significant effect on the tagging efficiency. In the above table, we take axial coupling as an example. For backgrounds, we set the trigger of a $m_{\ell+\ell^-}$ mass window as in the table to enlarge statistics.

Signal and Backgrounds

$m_{Z'}$ [GeV]	m_{H^\pm}			BKG
	100 GeV	140 GeV	160 GeV	
1	40.0	86.2	58.1	69.6
2	8.2	59.9	47.8	5.0
5	0.1	5.0	9.1	0.3

TABLE I: Expected number of events in each lepton-jet bin (20% window of the Z' mass) with two b -tagging in 8 TeV LHC 20 fb^{-1} . We set $X = 0.001$ and $\text{BR}(Z' \rightarrow \ell^- \ell^+) = 0.2$. Signal events were obtained with high order $\sigma_{t\bar{t}}$ with branching ratio, and the background events were obtained with tree-level simulation with $K_{\text{bkg}} = 2$.

- At 8 TeV, top pair production cross section $\sim 239 \text{ pb}$.
- For $m_{H^\pm} = 140 \text{ GeV}$, $M_{Z'} = 2 \text{ GeV}$,

$$N_{\text{sig}} = \sigma_{t\bar{t}} 2X \text{BR}(Z' \rightarrow \ell^+ \ell^-) \epsilon_{\text{sig}} L \approx 60$$

$$N_{\text{bkg}} = \sigma_{\text{bkg}} \epsilon_{\text{bkg}} L \approx 5$$

$$N_{\text{obs}} = N_{\text{sig}} + N_{\text{bkg}}$$

$$S_{\text{cL}} = \sqrt{2N_{\text{obs}} \log(1 + N_{\text{sig}}/N_{\text{bkg}}) - 2N_{\text{sig}}} \simeq 14.6$$

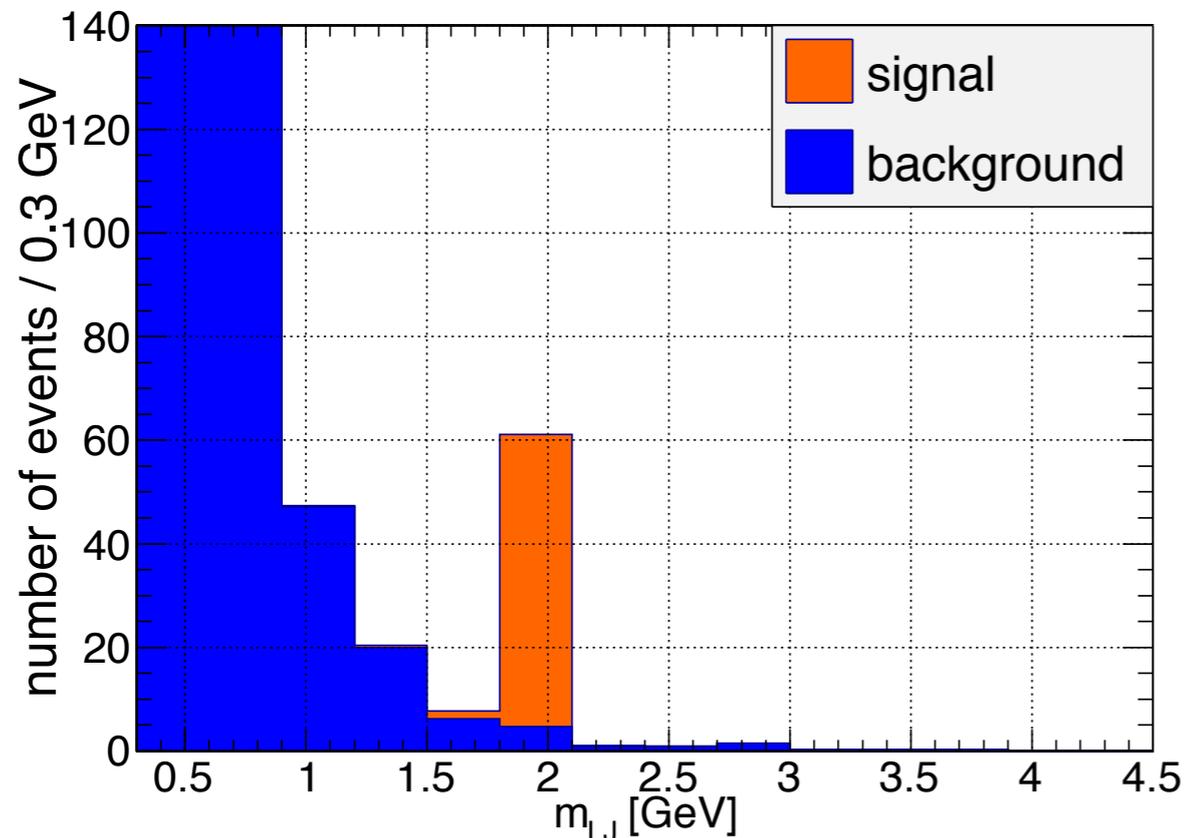

$m_{Z'}$ [GeV]	m_{H^\pm}		
	100 GeV	140 GeV	160 GeV
1	7.8 fb^{-1}	1.9 fb^{-1}	3.4 fb^{-1}
2	14.5 fb^{-1}	0.7 fb^{-1}	1.0 fb^{-1}
5	-	7.3 fb^{-1}	3.5 fb^{-1}

TABLE II: Required luminosity for 14 TeV LHC to see the likelihood ratio $S_{\text{cL}} = 5$ (corresponding to 5σ discovery). Basically the same method as Table I is used.

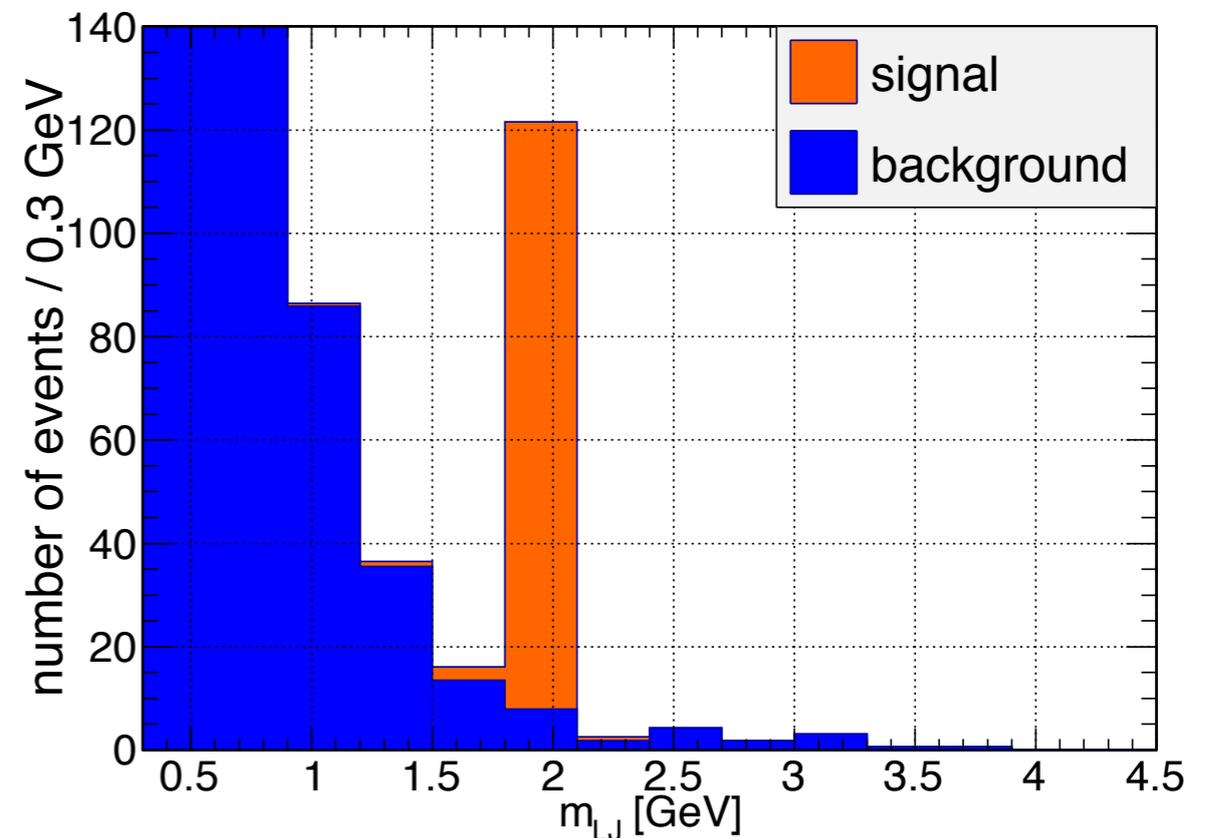

- Conventional search gives $N_{\text{sig}} \sim 4$ with $\text{eff} = 0.71\%$, and signal is buried in background uncertainty, which is 591.
- $N_{\text{bkg}} \simeq 1.7 \times 10^4$ results in $S_{\text{cL}} = 0.03$.
- Good sensitivity for LHC Run II.

Signal and Backgrounds

8 TeV LHC with 20 fb⁻¹

14 TeV LHC with 10 fb⁻¹

- At 8 TeV, top pair production cross section ~ 239 pb.
- For $m_{H^\pm} = 140$ GeV, $M_{Z'} = 2$ GeV,

$$N_{\text{sig}} = \sigma_{t\bar{t}} 2X \text{BR}(Z' \rightarrow \ell^+ \ell^-) \epsilon_{\text{sig}} L \approx 60$$

$$N_{\text{bkg}} = \sigma_{\text{bkg}} \epsilon_{\text{bkg}} L \approx 5$$

$$N_{\text{obs}} = N_{\text{sig}} + N_{\text{bkg}}$$

$$S_{\text{cL}} = \sqrt{2N_{\text{obs}} \log(1 + N_{\text{sig}}/N_{\text{bkg}}) - 2N_{\text{sig}}} \simeq 14.6$$

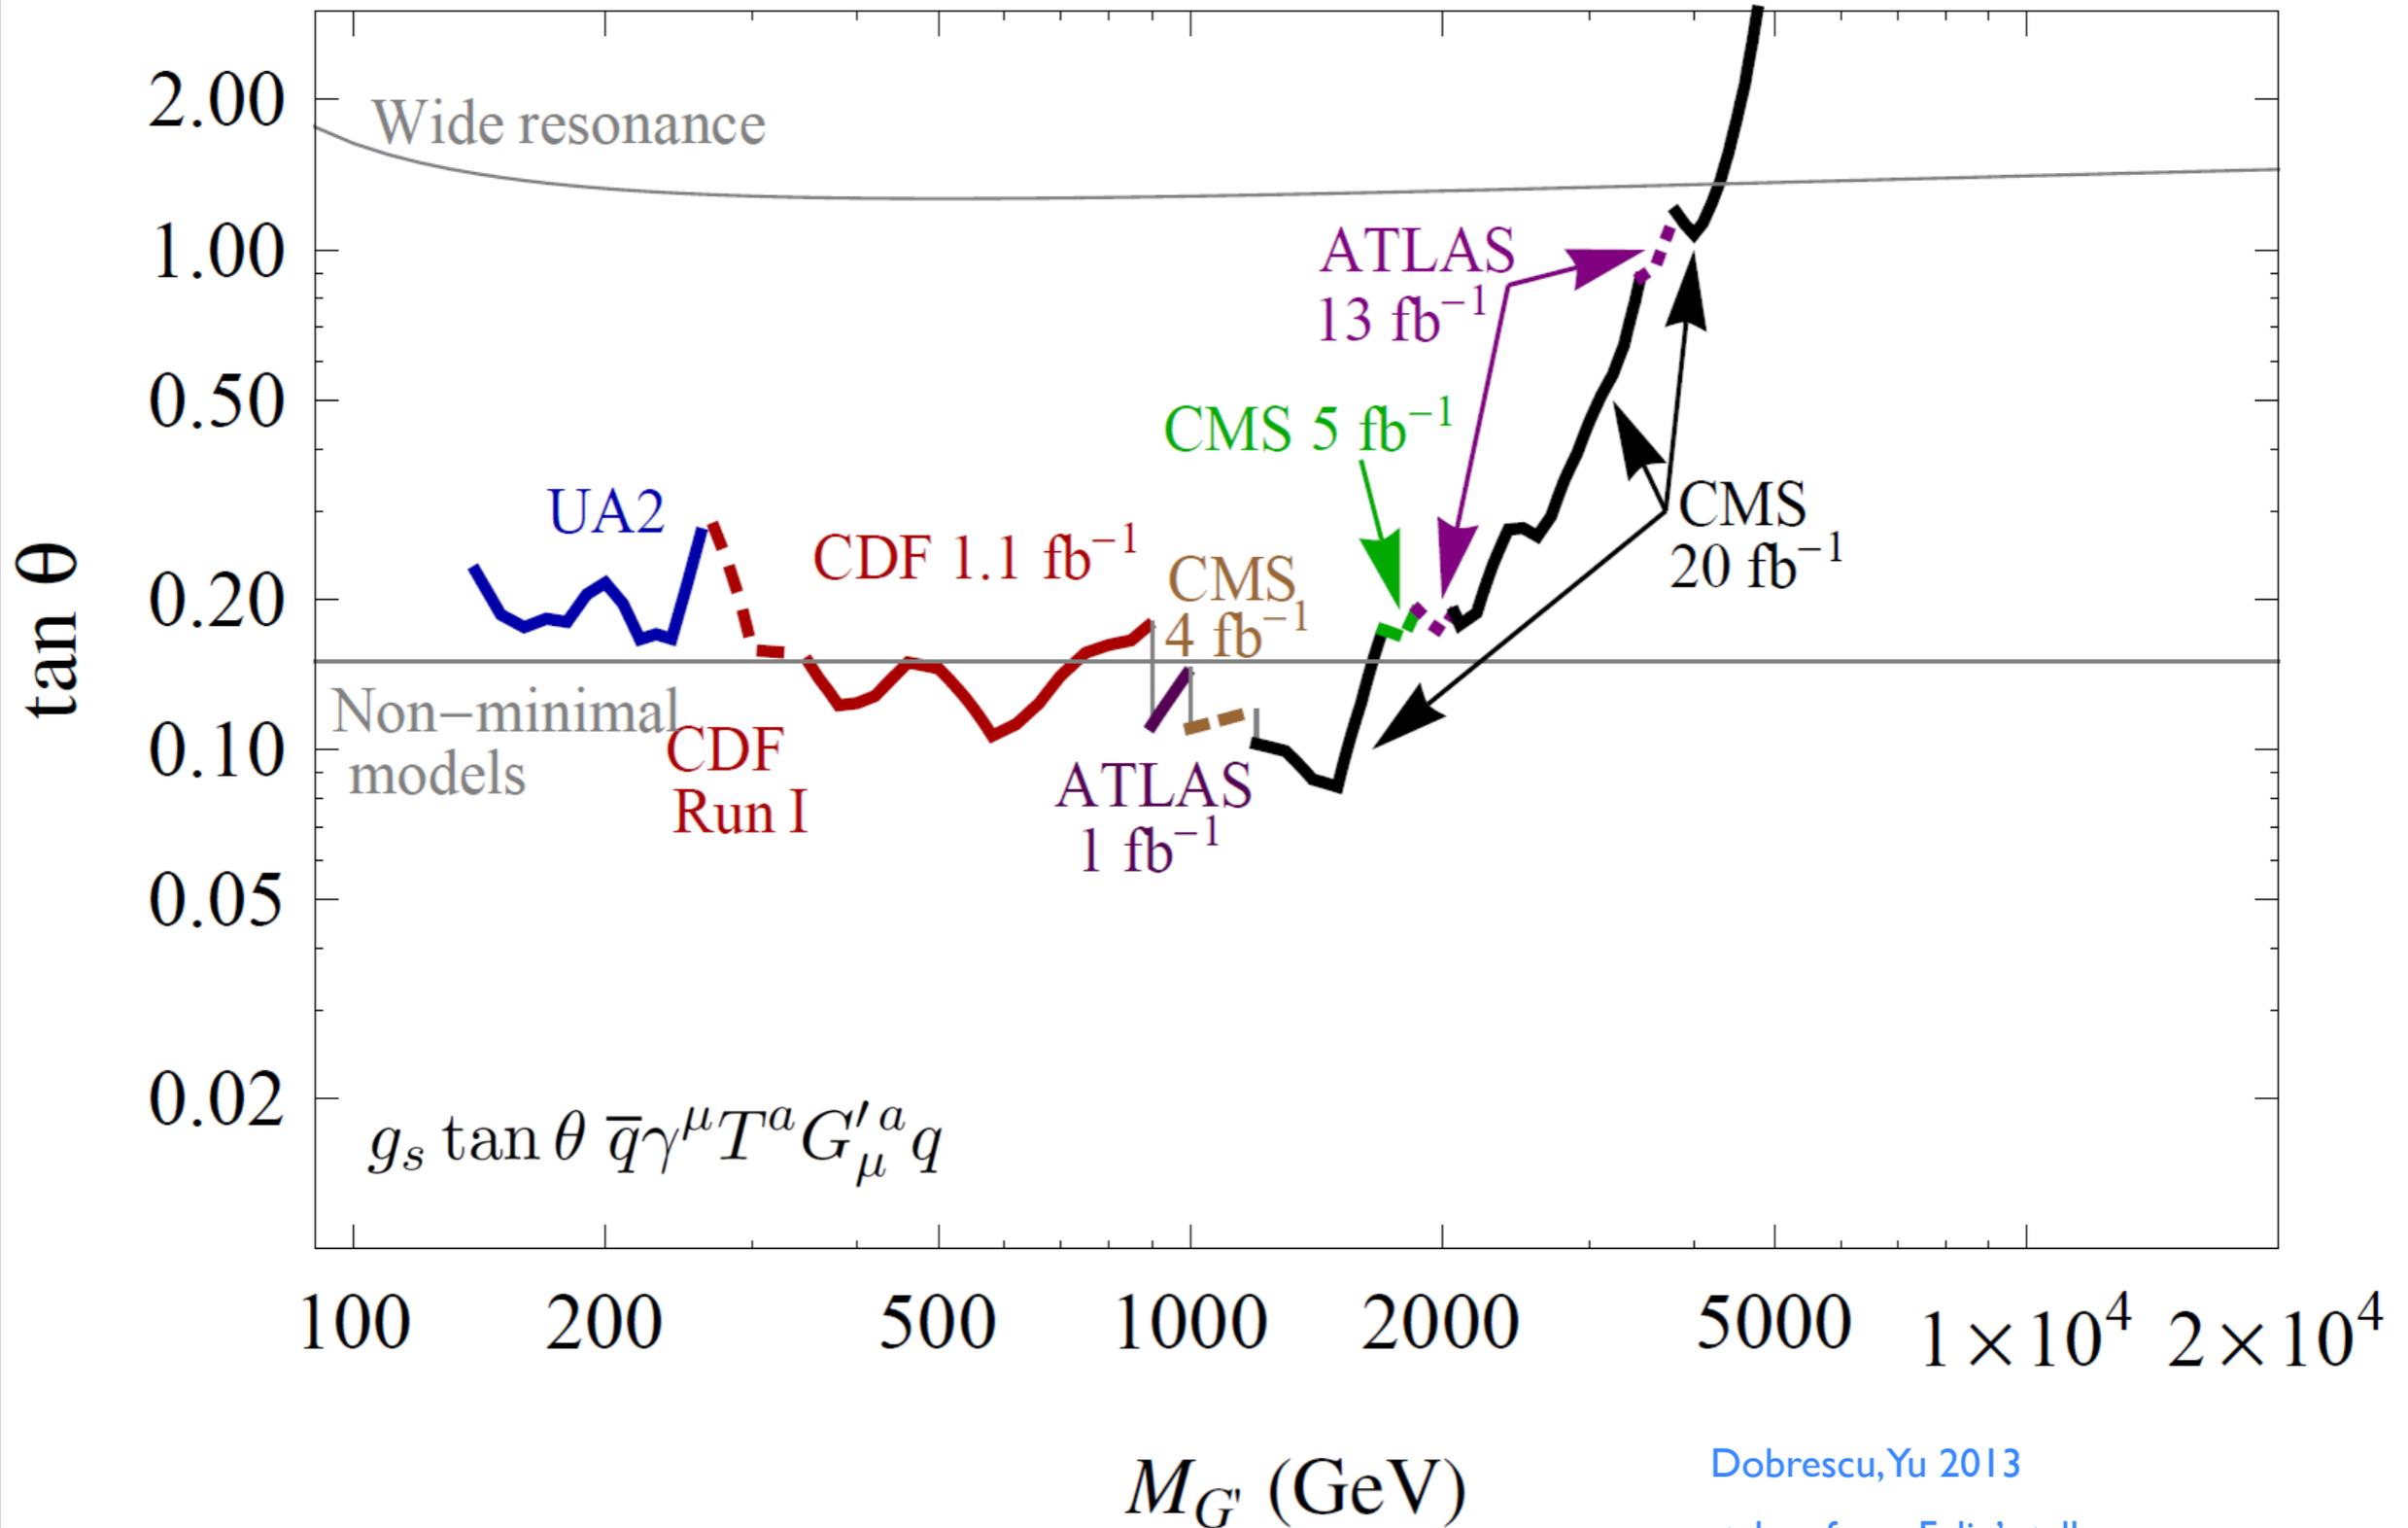

- Conventional search gives $N_{\text{sig}} \sim 4$ with $\text{eff} = 0.71\%$, and signal is buried in background uncertainty, which is 591.
- $N_{\text{bkg}} \simeq 1.7 \times 10^4$ results in $S_{\text{cL}} = 0.03$.
- Good sensitivity for LHC Run II.

A Light Dilepton resonance

- A light Zprime is well motivated and its search is very active at low energy experimental facilities.
- It also provides interesting collider signatures.
- It may be produced via top quark production.
- It decays to a collimated lepton pair, which may be missed by conventional searches.
- 8 TeV already rules out some parameter space.
- Exciting opportunity at LHC run II.

How do we look for a $tt\bar{b}\bar{b}$ (vector) resonance, if it does not couple to light quarks?
 (we call it 'g3' resonance)

It is not produced by $qq\bar{b}\bar{b}$ annihilation.

Perhaps we should be looking at different final states to look for such a $tt\bar{b}\bar{b}$ resonance.

Production of Top-Philic Resonance

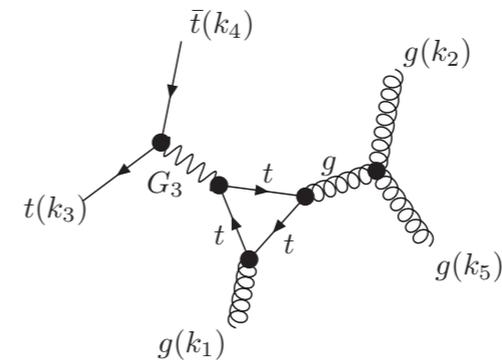

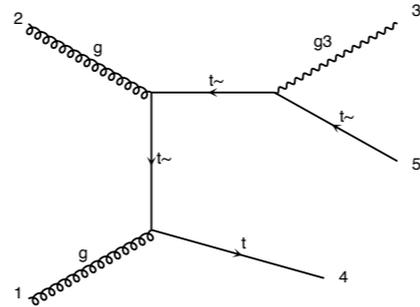

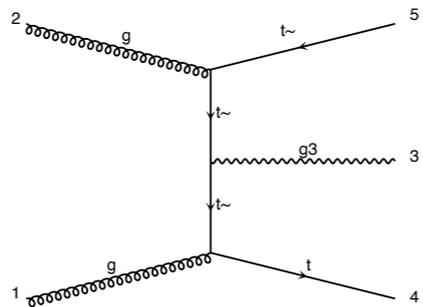

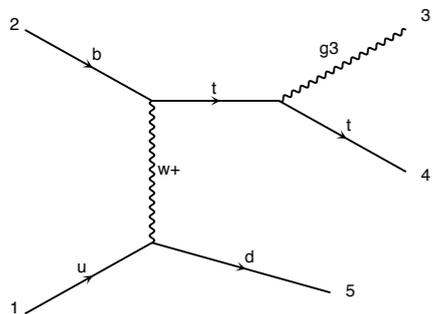

$$\mathcal{L} = \bar{t} \gamma_\mu (c_L P_L + c_R P_R) t G_3^\mu,$$

$$= c_t \bar{t} \gamma_\mu (\cos \theta P_L + \sin \theta P_R) t G_3^\mu$$

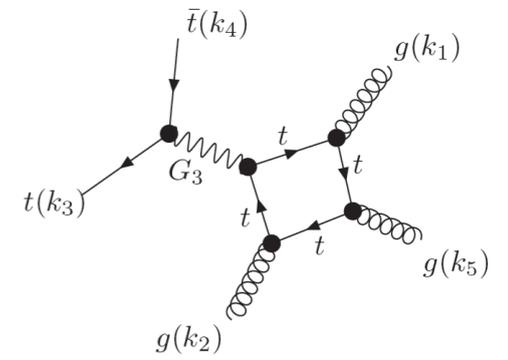

(a) four top-quark channel: $pp \rightarrow G_3 + t\bar{t} \rightarrow t\bar{t} + t\bar{t}$

(b) single top mode : $pp \rightarrow G_3 + t(\bar{t}) + j \rightarrow t\bar{t} + t(\bar{t}) + j$

(c) single top mode : $pp \rightarrow G_3 + t(\bar{t}) + W^\pm \rightarrow t\bar{t} + t(\bar{t}) + W^\pm$

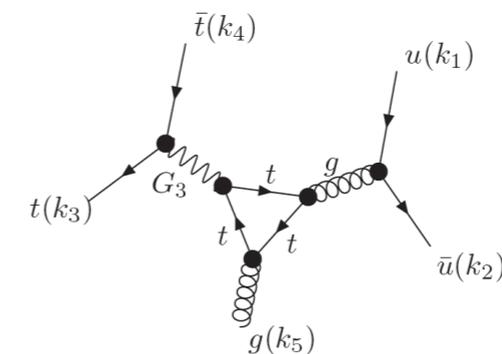

(a)

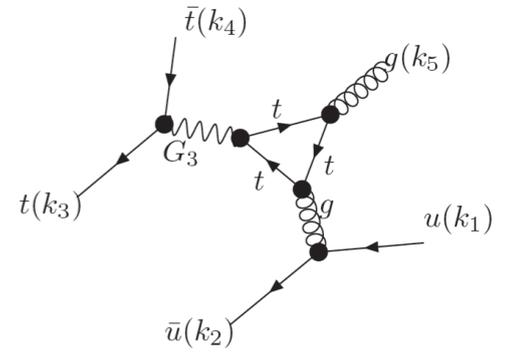

(b)

(a) loop induced $t\bar{t}j$: $pp \rightarrow G_3 + j \rightarrow t\bar{t} + j$

LHC 7 TeV		10	26	8...9	12
LHC 8 TeV		13			

Table 1: Overview of the $\Delta\sigma_{t\bar{t}}$ quantities, in pb, for the different limit categories concerning current inclusive (IX) and exclusive (EX) cross section measurements for $t\bar{t}$ production in association with $X = 0, 1$ jets.

Cross Section at One Loop

We should look at $t\bar{t}$ plus one jet instead of $t\bar{t}$, to search for a top-philic resonance.

To Compute One Loop Cross Section....

The virtual amplitudes at one loop have been generated with GOSAM [8, 9], a publicly available package for the automated generation of one-loop amplitudes. It is based on a Feynman diagrammatic approach using QGRAF [10] and FORM [11] for the diagram generation, and SPINNEY [12], HAGGIES [13] and FORM to write an optimized Fortran output. For the reduction of the tensor integrals we used NINJA [14, 15], an automated package for the integrand reduction via Laurent expansion. This package is a part of GOSAM and therefore no further work is required to use it. Alternatively one can use other reduction techniques such as integrand reduction using the OPP method [16–18] as implemented in SAMURAI [19] or using methods of tensor reduction as contained in GOLEM95 [20–22]. The remaining scalar integrals have been evaluated using ONELOOP [23].

- MG5_aMC@NLO will allow this computation much easier.
- These tools help to expedite early discovery!

Summary

- Exciting Opportunities at Run II in 2015.
- Continue with both 'model-dependent' and 'model-independent' searches but also think of new topologies and new channels that have not been searched for.
- Might need more systematic approaches to look for resonances.
- Eliminate common assumptions one by one.
- Nature could be more exotic than we expect!
